Abstract

The purpose of this study was to investigate the effects of chitosan oligosaccharides (COS) on the antioxidative function, lymphocyte cycle and apoptosis of ileum mucosa in broiler. 640 AA broilers were randomly allocated into four groups, which were fed with diets supplemented 0, 200, 350 and 500 mg/kg of COS for six weeks, respectively. The results showed that compared with the control group, the activities of glutathione peroxidase and superoxide dismutase, the ability of total antioxidant capacity and inhibit hydroxy radical as well as the contents of glutathione in the 350 and 500 mg/kg COS groups were significantly increased, while the levels of malondialdehyde were significantly decreased. The percentages of S and gap 2/mitosis (G2M) phases and proliferating index of ileum mucosal lymphocytes in the 350 and 500 mg/kg COS groups were increased, but, the percentages of apoptotic ileac lymphocytes were not significantly different compared with the control group. No significant difference in the levels of antioxidant function mentioned above, cell cycle phase distribution and the percentages of apoptotic ileac lymphocyte existed between the 350 and 500 mg/kg COS groups. Conclusion: dietary chitosan oligosaccharides supplements with 350 mg/kg and 500 mg/kg could improve the antioxidant function and accelerate lymphocytes proliferation, but had non-influence on lymphocytes apoptosis in the ileum mucosa of broiler.

Kitosan Oligosakkaritlerin Broiler İleum Mukozasında Antioksidan Fonksiyon, Lenfosit Döngüsü ve Apoptozis Üzerine Etkileri

Özet

Bu çalışmanın amacı; kitosan oligosakkaritlerin (COS) broiler ileum mukozasında antioksidan fonksiyon, lenfosit döngüsü ve apoptozisine olan etkilerini araştırmaktır. 640 AA broiler rastgele olarak dört gruba ayrılarak sırasıyla 0, 200, 350 ve 500 mg/kg COS içeren diyetle altı hafta süresince beslendi. Kontrol grubu ile karşılaştırıldığında 350 ve 500 mg/kg COS içeren diyetle beslenen gruplarda glutatyon peroksidaz, ve süperoksit dismutaz aktiviteleri, total antioksidan kapasite ile hidroksit radikalin inhibe etme kapasitesi ve glutatyon miktarı anlamlı derecede artmıştır. S yüzdesi ve gap 2/mitosis (G2M) fazları ile ileum mukoza lenfositlerinin çoğalma indeksi 350 ve 500 mg/kg COS içeren diyetle beslenen gruplarda artış göstermiştir, apoptotik iliac lenfositlerin yüzdesi anlamlı derecede kontrol grubundan farklılık göstermiştir. 350 ve 500 mg/kg COS içeren diyetle beslenen gruplar arasında yukarıda bahsi geçen antioksidan fonksiyon, hücre döngüsü faz dağılımı ve apoptotik iliac lenfosit yüzdesi farklılık göstermemiştir. Sonuç olarak, diyetten kitosan oligosakkaritlerin 350 ve 500 mg/kg oranında ilavesi broilerlerin ileum mukozasında antioksidan fonksiyonunu geliştirmelerini lenfosit çoşalmasını hızlandırmıştır, lenfositlerde apoptozis üzerine etki etmemektedir.

Anahtar sözcükler: Kitosan oligosakkaritler, Lenfosit, Antioksidan fonksiyon, Hücre döngüsü, Apoptozis
INTRODUCTION

In recent decades, chitosan has been used as one of additives in forage due to its various biological activities, including antitumor\(^{[1]}\), antioxidative\(^{[2]}\), immunopotentiating\(^{[3]}\) and some other health benefits \(^{[4]}\), but its high molecular weight and high viscosity may limit its use in vivo\(^{[5]}\). Chitosan oligosaccharides (COS) are the depolymerized products of chitosan, having similar or even better biological activities \(^{[6]}\). COS received wide-spread attention because of its solubility \(^{[7,8]}\), low toxicity to eukaryotes \(^{[4]}\), and immune-enhancing effects \(^{[9]}\), along with improvement in health status of human being and animals \(^{[10-13]}\).

The antioxidant activity of COS has been demonstrated in vitro and in vivo. In murine models, COS could reversed the decrease of glutathione (GSH) levels, and catalase (CAT) activity, and the increase of malondialdehyde (MDA) levels in the liver, lung and kidney from LPS-induced mice \(^{[14]}\). In Alzheimer's disease rat, COS treatment increased hippocampal superoxide dismutase (SOD) activity level \(^{[15]}\), and in another in vitro study, COS exerted antioxidative effects on pancreatic islet cells in streptozotocin-induced diabetes in rats \(^{[16]}\). HJ Yoon \(^{[17]}\) reported that the production of creatinine and MDA was increased and SOD was decreased in the glycerol-induced acute renal failure rats, and COS recovered aforesaid oxidative damage in kidney \(^{[17]}\). COS not only has antioxidative activities in aforementioned disease models, but also has a similar effect in normal animal such as *Penaeus monodon*, in which the total antioxidant status (TAS) and glutathione peroxidase (GSH-Px) activities of digestive gland in the COS diet group were higher than those in the control \(^{[18]}\).

It has been shown that COS can affect cell cycle and inhibit tumor growth. In the study of Liu et al.\(^{[19]}\), pre-incubation of COS with ECV304 cells for 24 h resulted in the induction of cell cycle arrest in G1/S+M \(^{[19]}\). Han et al.\(^{[20]}\) reported that COS could inhibit the proliferation of human lung cancer line HepG2 cells, and induce their G2/M phase arrest \(^{[20]}\). In another study, COS significantly inhibited the proliferation of three types of human gastric cancer cells (BGC823 cells, MKN45 cells and SGC7901 cells) after treatment for 48 h and the inhibition rate was positively correlated with the concentration of COS \(^{[21]}\). But, Jiang et al.\(^{[22]}\) demonstrated that the proliferation index and the expression of cyclin D1 of normal Schwann cells treated with 0.25, 0.5 and 1.0 mg/mL COS were increased when compared with those of control \(^{[22]}\).

Moreover, COS can affect the apoptosis process. It could induce various cells apoptosis, such as human colon cancer cells HT-29 \(^{[23]}\), SW480 cells \(^{[24]}\), AGS human gastric cancer cells \(^{[25]}\), hepatocellular carcinoma cells \(^{[26]}\), and human myeloid leukemia HL-60 cells \(^{[27]}\). Besides, 50-200 μg/mL COS treatment reversed the increasing of apoptotic articular chondrocytes by IL-1β-induced and downregulated the expression of Bax and caspase-3, and upregulated the expression of Bcl-2 of chondrocytes \(^{[28]}\).

Intestinal tract is the body's structure which contacts with various antigens including bacteria, virus, parasites, sitotoxin and medicines. As part of the intestinal tract, the ileum is the major component of the gastrointestinal tract and its mucosal immune system plays an important role in the intestinal immune function. The lymphocytes of mucosa take part in mucosal immunity, their proliferation and apoptosis are one of the bases of the mucosal immune system operation. Early researches have shown that effects of COS on antioxidant role, cell cycle and apoptosis were mainly focused on tumors or disease models, and information concerning these areas on normal intestine was not available. The aim of this study was to investigate the effects of COS on antioxidant function, lymphocyte cycle and apoptosis in ileum mucosa of broiler by the methods of biochemistry and flow cytometry.

MATERIAL and METHODS

Animals and Diets

Six hundred and forty one-day-old male AA chicken were randomly and equally divided into four groups with eight replicate per group, that is, control group, COS-A group, COS-B group, COS-C group (the degree of deacetylation of COS exceed 95%, the molecular weight of COS was less than 2000 DA, ZTH Tech. Co., Beijing, China). All animal studies were approved by the Animal Ethics Committee of Sichuan Agricultural University (Approval no. 2012-024). Chickens were housed in coops with electrically heated units and provided with water and diet ad libitum for 42 days.

In all experiments, the basal diet was a typical corn-soybean diet which was formulated to meet standards of National Research Council \(^{[29]}\). COS was mixed into the corn-soybean basal diet to constitute the experimental diets with 200 mg/kg, 350 mg/kg and 500 mg/kg of COS for COS-A, COS-B and COS-C groups, respectively (Table 1).

Detection of Antioxidant Function in Ileum Mucosa

At 21 and 42 days of age during the experiment, eight broilers of each group were sacrificed and ilea were immediately removed and chilled to 0°C in normal saline (ileum was defined as the segment before the ileocecal junction equalto the length of the ceca \(^{[30]}\)). An approximately 4-cm length of tissue was collected from the middle of ileum. Then, each sample was dissected longitudinally and washed in normal saline. The mucosae were carefully scraped from the inner surface of the each sample. Each sample was weighed, immediately transferred into a centrifuge tube, added nine-volumes of ice-cold 0.85% NaCl solution and homogenized. The homogenized solution was immediately centrifuged at 3500xg for 10

According to Bradford method [31], the concentration of total protein in the supernatant of mucosa homogenate was determined. The activities of SOD, GSH-px, and ability of total antioxidant capacity (T-AOC); and ability to inhibit hydroxyl radical (IHR), and contents of MDA and GSH in the supernatant were detected by biochemical methods following the instructions of the corresponding reagent kits (SOD: Cat. NO. A001-1; GSH-px: Cat. NO. A005; ability of T-AOC: Cat. NO. A015; ability to IHR: Cat. NO. A018; MDA: Cat. NO. A003-1; GSH: Cat. NO. A006, All of these kits were purchased from Nanjing Jiancheng Bioengineering Institute of China, Nanjing, China). The absorbance of total protein in the supernatant of mucosa homogenate was measured at 520, 450, 532, 412, 420 and 550 nm using microtiter plate reader (Thermo, Varioskan Flash, USA), respectively.

Detection of Lymphocytes Cell Cycle of Ileum Mucosa

The mixture of Intra-EPithelial Lymphocytes (IELs) and Lamina Propria Lymphocytes (LPLs) were isolated and detected by Flow Cytometer (FCM). Briefly, at 21 and 42 days of age during the experiment, eight broilers of each group were humanely killed. The ilea were immediately removed and placed in petri dishes containing chilled (4°C) RPMI-1640 (Catalog No. SH4007-13, LOT: MXL0747, Hyclone, Logan, UT, USA). Then ilea were opened longitudinally and placed in petri dishes containing chilled (4°C) RPMI-1640 medium and then transferred to a preparatory 50 mL tube after EDTA treatment (as described in the isolation of IELs). The tubes were incubated horizontally at 37°C for 30 min in a shaking-water bath. The contents of each tube were transferred to petri dishes and 200 μL FCS were added. The ileal mucosa was compressed with a syringe plunger over a plastic mesh. Single cell suspensions containing lamina propria cells were filtered through organdy mesh and then centrifuged 10 min at 2500× g. LPLs were collected and centrifuged in a discontinuous 40/70% Percoll gradient at 600× g for 30 min. Cells collected from the interface were washed and suspended in RPMI-1640 medium with 1% FCS, and then centrifuged at 200× g for 5 min. The cell density was diluted to 1.0×10⁶ cells/mL with PBS. Then 1 mL mixture of IELs and LPLs were transferred to a 5-mL centrifuge tube and centrifuged at 200×g for 5 min. The supernatant was discarded, and 1 mL PI staining solution (5 μL/mL propidium iodide, 0.5% Triton X-100, 0.5% RNase, PBS) was added. The cells were gently vortexed and incubated for 20 min at room temperature (25°C) in the dark. 2 mL PBS were added. The cells were re-suspended in 0.5 mL PBS and the cell phases were analyzed by flow cytometry (FACSCalibur, BD, Franklin Lake, NJ, USA).

The proliferating index (PI) was calculated through the following formula:

\[
PI = \frac{(S+G₂M) \times 100\%}{(G₀G₁+S+G₂M)}
\]

Detection of Lymphocyte Apoptosis of Ileum Mucosa

The aforementioned proper concentration (1.0×10⁶ cells/mL) mixture of IELs and LPLs (100 μL) was transferred to a 5-mL flow tube and 5 μL of Annexin V-FITC (Cat. No. 51-65874X, BD Pharmingen, Santiago, CA, USA) and 5 μL of propidium iodide (Cat. No. 51-66211E, BD Pharmingen, Santiago, CA, USA) were added. The samples were slightly vortexed and incubated for 15 min at room temperature (25°C) in the dark. 400 μL PBS was added to each sample and percentages of apoptosis were determined by flow cytometry (FACSCalibur, BD, Franklin Lake, NJ, USA).
**Statistical Analysis**

The significance of difference between four groups was analyzed by variance analysis, and SPSS 17.0 for Windows was used for statistics calculation. The results were presented as mean± standard deviation (X±S), and a value of P<0.05 was considered significant results data.

**RESULTS**

The changes of antioxidant function in the ileum mucosa were shown in Fig. 1. Compared with the control group, the values of GSH-Px, SOD, GSH, T-AOC and IHR in the COS-B and COS-C groups were significantly increased (P<0.05 or P<0.01), while the levels of MDA in the COS-B and COS-C groups were significantly decreased (P<0.05 or P<0.01). However, no significant changes of antioxidant function in the COS-A group were noted (P>0.05) when compared with the control group except for values of T-AOC and IHR which were significantly increased (P<0.05 or P<0.01). Furthermore, no significant difference in the levels of antioxidant function existed between the COS-B and COS-C groups (P>0.05) (Fig. 1).

As shown in Table 2, compared with the control group, the percentages of G0/G1 phase lymphocytes in the COS-B and COS-C groups were obviously decreased (P<0.05 or P<0.01), while the percentages of G2/M phase, S phase and PI value were increased (P<0.05 or P<0.01) at 21 and 42 days of age except for the percentage of G2/M phase at 21 days of age. However, the percentages of G0/G1, G2/M and S phase as well as PI value in the COS A group were not significantly different from those in the control group (P>0.05) except for the percentages of S phase (P<0.05). In addition, no significant difference in the percentages of lymphocyte cycle existed between the COS-B and COS-C groups (P>0.05) (Table 2).

As shown in Table 2, no significant changes in the percentage of apoptotic lymphocytes in ileum mucosa among four groups were observed (P>0.05).

DISCUSSION

Oxidative stress results when production of ROS exceeds the capacity of cellular antioxidant defenses to remove these toxic species [32], and antioxidant exerts its role in vivo or in food mostly via inhibiting generation of ROS, or scavenging free radicals [33]. Some antioxidant enzymes, such as SOD and CAT, are considered to be the first line of cellular defense against oxidative damage by scavenging free radical [34,35]. Hydroxy radical can cause oxidative stress and GSH is regarded as an early biological marker of oxidative stress [35]. The MDA production induces alteration of membrane fluidity and increase of membrane fragility [36-38]. Early research has shown that LPS could result in oxidative damage, in which the GSH levels and the CAT activity decreased while the MDA levels increased in mice after LPS injection [14]. However, pre-injection 100 mg/kg COS could smooth out the oxidative stress [33]. COS is a potent radical scavenger, which has the high scavenging activity of ROS [33]. Some antioxidant enzymes, such as SOD and CAT, are considered to be the first line of cellular defense against oxidative damage by scavenging free radical [34,35]. Hydroxy radical can cause oxidative stress and GSH is regarded as an early biological marker of oxidative stress [35]. The MDA production induces alteration of membrane fluidity and increase of membrane fragility [36-38]. Early research has shown that LPS could result in oxidative damage, in which the GSH levels and the CAT activity decreased while the MDA levels increased in mice after LPS injection [14]. However, pre-injection 100 mg/kg COS could smooth out the oxidative stress [33]. COS is a potent radical scavenger, which has the high scavenging activity of ROS [33]. Some antioxidant enzymes, such as SOD and CAT, are considered to be the first line of cellular defense against oxidative damage by scavenging free radical [34,35]. Hydroxy radical can cause oxidative stress and GSH is regarded as an early biological marker of oxidative stress [35]. The MDA production induces alteration of membrane fluidity and increase of membrane fragility [36-38].

The cell cycle is a ubiquitous and complex process, and it can be subdivided into G1, S, G2, and M phases. The S phase of cell cycle is define as the period during which DNA is replicated; G2: the period between completion of DNA synthesis and mitosis; M: from prophase to telophase. Our results show that compared with the control group, the percentages of S and G2M phase and PI index of lymphocytes in the COS-B and COS-C groups were generally increased, suggesting dietary COS supplements with 350 mg/kg and 500 mg/kg could accelerate cell proliferation of lymphocytes in the ileum mucosa. This was accord with previous studies, in which COS enhanced immunity via accelerating T-cell differentiation and maintain T-cell activity [43], and treatment of primary Schwann cells with COS promoted cell proliferation as determined by cell cycle analysis [22]. The cell cycle is controlled by numerous mechanisms ensuring correct cell division, for example, cyclin-dependent kinases (CDK) (a family of serine/threonine protein kinases), which belongs to a family of serine/threonine protein kinases that are activated at specific points of the cell cycle [44]. The three D type cyclins (cyclin D1, cyclin D2, cyclin D3) bind to CDK4, CDK6 and CDK-cyclin D complexes are essential for entry in G1 phase [45]. Cyclin A binds with CKD2 and this complex is required during S phase [46]. Previous studies demonstrated that COS could downregulated Cdk-2 and cyclin A of HepG2 cells to inhibited cell proliferation [47], and COS also could increased the cyclin D1 expression of normal neural glia cells [23]. Whether the mechanism of COS affects lymphocytes cycle in the ileum mucosa observed in this study was also related to cyclin-dependent kinases (CDKs), further studies are needed since numerous factors control the progression of the cell cycle.

Early researches have shown that COS has the tumor inhibitory effect, inducing various tumor cells apoptosis [26,27,48-52]. Also, COS had anti-apoptosis effect in IL-1β-induced chondrocytes apoptosis on osteoarthritis model.
