Abstract

The effect of ozone treatment in experimental rat gout arthritis was investigated. Twenty adult albino male rats were divided into 4 groups: Group 1 (Control) was followed without any medication, Group 2 (Gout control) was injected with a single dose of 0.2 mL (10 mg) monosodium urate (MSU) intraarticularly to 1st metatarsophalangeal joint to create experimental Gouty arthritis. Group 3 (Gout + Ozone) was injected intraarticularly to 1st metatarsophalangeal joint with a single dose of 0.2 mL (10 mg) MSU to generate experimental gout, followed by ozone therapy to the rats a single dose of 1 mL (10 µg/mL) intraperitoneally daily for 3 weeks. The Group 4 (Ozone control) ozone therapy was given a single dose of 1 mL (10 µg/mL) intraperitoneally daily for 3 weeks without gout formation. The results were recorded and compared statistically between the groups. In conclusion, the low level of inflammation in the third group (Gout + Ozone) was considered statistically significant as compared to the second group. With Ozone treatment the gout joint has been shown to have reduced acute inflammation, it has not been affected by the chronic proliferation process.

Keywords: Gout, Ozone, Immunomodulators, Anti-inflammatory agents

INTRODUCTION

Gout disease is the most common cause of inflammatory arthritis in adults at the time of the US registry [1]. Gout disease is a chronic disorder associated with self-limiting acute gout attacks (gout flare), caused by accumulation of monosodium urate crystals in the synovial fluid.
of monosodium urate (MSU) deposits in joints and surrounding soft tissue and bursa [1]. Acute attacks of gout disease are one of the most important causes of adverse health-related quality of life [2-3]. It has also been reported that 12 to 15% of individuals aged 40-60 years worldwide have hyperuricemia and 3% are affected with gout arthritis [4]. As the molecular basis of gout disease, oxidative stress has been noted in studies that have shown promise in the pathogenesis of gout.

In the extracellular compartment, the uric acid molecules are present in 98% of the MSU at dense sodium concentration and physiological pH. If the urate concentration exceeds 6.8 mg/dL, the urate molecules will crystallize and precipitate and play a role in the initiation of the inflammatory reaction. In addition to exceeding the value of the urate density, conversion to MSU crystal formation is also implicated in a number of factors such as ambient temperature, hydrogen ion formation, concentration of cations, and the viscosity of the joint fluid [5-6]. This suggests that Gout arthritis is more common in peripheral joints, such as the first metatarsophalangeal joint [7]. MSU crystals are detected and presented to phagocytes by receptors such as Toll-Like Receptor (TLR) 1 and 2 and surface antigens such as CD14 [8-9]. In this context, anti-inflammatory treatments have found wide use in the treatment of gout arthritis, especially acute gout attack (gout flare) and chronic gout prophylaxis. These include interleukin 1 antagonists (anakinra, canakinumab, rilonacept), uricosuric drugs (probenecid, benz bromarone), xanthine oxidase inhibitors (allopurinol, febuxostat), cyclooxygenase 2 (COX2) inhibitors, colchicine and steroids that inhibit the migration of inflammatory cells [10].

Medical ozone treatment consists of 95% Oxygen (O2) and 5% Ozone (O3) mixture. The present rates are therapeutic ratios. There is toxic effects of ozone (O3) ratio above 5% in ozone treatment [11]. On the other hand, ozone therapy has shown that ozone can be safely used at doses between 10 and 80 µg/mL and immunomodulators, anti-inflammatory, bactericidal, antifungal and analgesic effects are at these doses [12]. Medical ozone therapy affects anti-inflammatory activity in two phases. Studies have shown that in the first phase, the levels of proinflammatory mediators such as prostaglandin E2, phospholipase A2, cyclooxygenase I-II, callicrein and bradykinin are reduced. In addition, ozone treatment reduces levels of molecules responsible for joint destruction such as metalloproteinase, collagenase, and gelatinase. In the second phase, ozone therapy increases the levels of antioxidant enzymes, molecules and cytokines. Examples include oxidative shock proteins (hemo-oxygenase-1), Interleukin 4 and Interleukin 10, Transforming Growth Factor-β (TGF-β). It has also been shown that ozone therapy induced new vessel formation (neangiogenesis), increases nitric oxide (NO) endorphin, adrenocorticotropic hormone (ACTH) and cortisol levels [13].

In the face of this wide spectrum of activities, today’s ozone therapy is available in many different system diseases such as osteomyelitis, chronic obstructive pulmonary disease, hepatitis, cystitis, rheumatoid arthritis, osteoarthritis, back pain, multiple sclerosis and coronary artery disease [14]. The aim of our study was to examine the effects of nontoxic ozone administration on the gout-induced joint model in therapeutic doses and to create an alternative to current in the future.

MATERIAL and METHODS

Following approval from the Kafkas University Local Experimental Animals Ethics Committee (KAU-HADYEK/2017-012) twenty adult albino male rats were used in the study. Rats were randomly divided into 4 groups and group 1 (Control, n=5) was followed up without any drug. 0.2 mL (10 mg) MSU was injected intra-articularly to 1st metatarsophalangeal joint through the right footpad to create experimental gout in the 2nd group (Control group, n=5) and was followed without additional treatment. A single dose of 0.2 mL (10 mg) O3 MSU was injected intraarticularly to 1st metatarsophalangeal joint through the right footpad to create an experimental gout in group 3 (Gout + Ozone, n=5) followed by intraperitoneal 1 mL (10 µg/mL) ozone therapy daily in rats. Group 4 (ozone control, n=5) Ozone therapy was administered intraperitoneally 1 mL (10 µg/mL) daily without gout.

Group 3 and group 4 administered once daily dose of 1 mL (10 µg/mL) ozone therapy daily in rats. Group 4 (ozone control, n=5) Ozone therapy was administered intraperitoneally 1 mL (10 µg/mL) daily without gout. Group 3 and group 4 administered once daily dose of 1 mL (10 µg/mL) intraperitoneally for 3 weeks. After 3 weeks of treatment, euthanasia was performed according to the condition of the rats and then the right hind paws were cut, and histopathology examined.

RESULTS

Confirmed radiological imaging of rats with gout (Fig. 1). The pathological results of the groups were compared statistically (P=0.003) (Table 1). In addition, the rate of suppression of inflammation in the ozone group was significantly higher than the control group (P=0.005). On the other hand, no statistically significant inflammation was observed in the 4th group which was given only ozone according to the control group (P=0.03). Control group (1st group) and ozone control group (4th group) and gout control group (2nd group) and ozone control group (3rd group) were compared between each other in terms of epithelization (Fig. 2A,B,C,D). There was no statistically significant difference between the groups.

DISCUSSION

Gout is a common disease that causes severe pain and loss of work power during an acute exacerbation. The etiopathogenesis has been well researched with a wide range of treatments ranging from monoclonal antibody therapy to anti-inflammatory therapy in the treatment
of the disease. These treatments are given in the form of step-by-step treatment and are constantly updated as both side effects and treatment costs are considered. Glucocorticoids and non-steroidal anti-inflammatory drugs are the leading cost-effective treatments for gout. Although its efficacy in long-term therapy has been proven, alternative forms of treatment are still needed in terms of potential side effects (Chronic Renal Failure, Diabetes Mellitus, Cushing Syndrome). In addition, xanthine oxidase inhibitors (allopurinol), selective xanthine oxidase inhibitor (febuxostat), drugs that increase uric acid excretion (losartan, fenofibrate), turgous drugs (rasburicase) that provide resorption of tofus are tested among current medical treatments. In the treatment of gout, two main titles are being considered today; to reduce the uric acid increase and to minimize the destructive effect of increased uric acid.

Ozone treatments instead of conventional therapy have been experimented on for many diseases because of the better understanding of the mechanism of action and lowering of treatment costs. It has been shown that ozone
The Investigation of the Effect of ...  

...treatment reduces serum uric acid levels in patients with osteoarthritis and also reduces VAS (visual analogue scale) and WOMAC (Western Ontario and Mac master index) scores and reduces joint pain [17,18]. Li and Ni [19] evaluated gut arthritis-associated pain-associated VAS scores in their study of ozone at a dose of 20 μg/mL on subjects with gout disease and found that the VAS score fell from 5.35±2.78 to 3.30±2.21. As mentioned above, although there are studies in which the ozone treatment is given in the form of major hemotherapy in hyperuricemic patients and intraarticular in osteoarthritic patients, there is no study in the literature which examines the ozone effect in experimental gout joints. In ozone-treated patients, as indicated in other publications, it has been shown that the molecules responsible for joint destruction are reduced. In the study we conducted, a significant proliferation increase in the ozone Gout group was observed compared to the control group. Bilge et al.[20] studies on ozone treated rats with osteomyelitis found higher total serum antioxidant capacity and histopathologically found more positive results in terms of inflammation and abscess formation. Similarly, in our study ozone-induced inflammation was significantly suppressed. Although our study did not prevent the formation of proliferation or reactive epithelium when given intraarticularly, it showed suppressed inflammation, and there was no significant pathologic change in the joints in the osteonecrosis test group 4. As a result, intraarticular ozone treatment was considered to be one of the advanced treatment options considering the potency and efficacy in Gout.
