Abstract

*Staphylococcus pseudintermedius* is a member of the *Staphylococcus intermedius* group (SIG) comprising representatives with similar phenotypic characteristics. The purpose of this study was to optimise a method for accurate differentiation of *S. pseudintermedius* in clinical samples from dogs and cats based on PCR-RFLP analysis, following the key biochemical tests for SIG group assignment, and to determine the prevalence of *S. pseudintermedius* compared to other members of the SIG group. To implement this, 158 isolates from dogs and 17 from cats, 4 reference strains - *S. intermedius* ATCC 29663, *S. pseudintermedius* LMG 22219, *Staphylococcus delphini* ATCC 49171, *Staphylococcus aureus* ATCC 25922 and 5 field strains of *S. aureus* were analysed. The generated PCR-RFLP profile (*pta* gene, *MboI* restriction enzyme) clearly differentiated *S. pseudintermedius* within the SIG group by having two distinctive bands of 213 and 107 bp, respectively. The data showed a predominance of *S. pseudintermedius* in clinical samples from dogs, while no *S. pseudintermedius* were found among the cat’s samples. In conclusion, due to the atypical biochemical reactions found in some *S. pseudintermedius* isolates (14.6%), precise identification should be based on an extensive phenotypic assay together with a molecular biological method or the latter alone.

INTRODUCTION

*Staphylococcus* spp. are Gram-positive bacteria causing a variety of opportunistic infections in humans, domestic and wild animals [1]. Usually, the pathogenicity of these bacteria is associated with the production of coagulase enzyme, on the basis of which they are defined as coagulase-positive and coagulase-negative, respectively. The following coagulase-positive/variable species are essential for veterinary medicine - *Staphylococcus aureus*, *Staphylococcus intermedius*, *Staphylococcus schleiferi* subsp. *coagulans*, *Staphylococcus hyicus*, *Staphylococcus lutrae*, *Staphylococcus delphini* and *Staphylococcus pseudintermedius* [2,3], while coagulase-negative species are considered significant when isolated from sterile body sites or in community-acquired infections [4].

Until recently, *S. intermedius* was thought to be commensal on the skin and mucous membranes of various animal species such as dogs, cats, pigeons, minks, horses, foxes, raccoons, goats and gray squirrels [5]. According to Wang et al. [6], *S. intermedius* is the predominant bacterial agent responsible for the etiology of the superficial pyoderma and soft tissue infections in dogs. With the development of advanced molecular methods, in particular DNA sequencing technologies, a group of researchers have clarified that the isolates identified as *S. intermedius* by phenotype methods actually a compound of three species - *S. intermedius*, *S. pseudintermedius* and *S. delphini*, which form together the *Staphylococcus pseudintermedius* group (SIG) [2]. Subsequently, based on DNA-DNA hybridization techniques and multilocus sequence typing (MLST), it was found out that the main bacterium responsible for the etiology of skin infections in dogs, cats and humans was practically *S. pseudintermedius*, and *S. intermedius* colonised mainly pigeons. Thus, the earlier scientific publications describing *S. intermedius* are now regarded as reports on *S. pseudintermedius* [7,8]. In addition, the clinical significance of *S. delphini* isolated from different animal species is considered greater than previously thought [10,11].

The misidentification of the SIG group representatives is due to the high degree of similarity in their phenotypic characteristics, as well as the existence of different biotypes of *S. intermedius* showing 50 to 65% DNA homology, which can be different species such as *S. delphini* and *S. pseudintermedius* [5]. On the other hand, genetic methods for differentiating microbial species based on the 16S rRNA gene are useless in these staphylococci because of the established gene similarity of over 99% [2,12]. The literature overview reveals several genetic approaches for the identification of *S. pseudintermedius* such as - PCR-RFLP analysis, nuc-PCR, sodA /hsp60 sequencing, and MALDI-TOF-MS analysis [3,8,13,14].

The purpose of this study was to optimise a method for accurate identification of *S. pseudintermedius* in clinical samples from dogs and cats based on the standard polymerase chain reaction with subsequent restriction of amplified fragments - PCR-RFLP analysis, following the key biochemical tests for SIG group assignment, and to determine the prevalence of *S. pseudintermedius* compared to other members of the SIG group.

MATERIAL and METHODS

**Bacterial Strains**

One hundred and seventy five isolates relevant to the SIG group - from dogs (n=158) and cats (n=17), 4 reference strains as controls - *S. intermedius* ATCC 29663, *S. pseudintermedius* LMG 22219, *S. delphini* ATCC 49171, *S. aureus* ATCC 25922, as well as 5 field *S. aureus* strains of cow, sheep, chicken, dog and rabbit origin were included in the study. Clinical specimens from dogs included ear discharge (n=48), skin lesions (n=42), ocular discharge (n=29), wound discharge (n=17), urine (n=8), material of oral tongue and gingival lesions (n=11) and synovial fluid (n=3). Cat isolates originated from skin lesions (n=9), urine (n=5), and ear discharge (n=3). Samples were cultured on trypticase soy agar (Fluka, India) supplemented with 5% defibrinated sheep blood and on MacConkey agar (NCIPD, Bulgaria; HiMedia, India). The plates were incubated under aerobic conditions at 37°C for 24-48 h. The initial identification of significant staphylococcal species was based on Gram’s staining, production of catalase and cytochrome oxidase enzymes, colonial characteristics and pigmentation, presence of complete haemolysis and the tube coagulase test with lyophilised rabbit plasma (NCIPD, Bulgaria).

**Biochemical Profile**

The biochemical profile of the isolates was determined on the basis of the following key tests: acetoin production in liquid medium with glucose, detection of β-galactosidase (4 mg disks, HiMedia, India), sensitivity to polymyxin B (300 U/disk, Oxoid, UK), utilisation of mannitol on mannitol-salt agar (NCIPD, Bulgaria), of trehalose and maltose in liquid media (MkB Test, Slovak republic).

The tests were carried out in accordance with the manufacturer’s instructions and the general rules for aseptic work in the microbiology laboratory [13].

Additionally, reference strains from the SIG group as well as selected clinical isolates were analysed with a semi-automatic BioLog phenotype identification system (BioLog, USA) with GenIII microplates according to the manufacturer’s instructions. Briefly, wells were loaded with 100 μL of bacterial suspensions at a density of 90-98% determined on a turbidimeter (BioLog, USA) and the plates incubated at 33°C for 20-24 h.

**PCR-RFLP Analysis**

DNA was isolated using a QIAGEN commercial DNA mini kit (Quiagen, GmbH, Germany) following the Gram-positive bacteria protocol requiring pre-treatment of the bacterial
stock with buffer containing 20 mg/mL lysozyme, 20 mM Tris HCl with pH 8.0, 2 mM EDTA and 1.2% Triton. DNA quality was determined spectrophotometrically at A260/A280 on a Gene Quant 1300 apparatus (Healthcare BioSciences AB, Sweden). The extracts were stored at -20°C until the start of the experiments.

PCR was performed with the primers targeting amplification of a 320 bp fragment of the phosphoacetyl transferase (pta) gene. The sequences of primers as follows: pta f1, AAA GAC AAA CTT TCA GGT AA and pta r1, GCA TAA ACA AGC ATT GTA CCG [13]. The PCR reaction adjusted in a final volume of 20 μL was as follows: primers 0.25 μM, 1 x PCR buffer, MgCl$_2$ 1.5 mM, dNTPs 0.2 mM, Taq polymerase 0.5 U/rxn (Canvax, Spain) and DNA 1 μL. The thermal conditions were adjusted in a gradient PCR machine included: initial denaturation at 95°C for 2 min followed by 30 cycles consisting of denaturation at 95°C for 60 sec, annealing at 53°C for 60 sec, elongation at 72°C for 60 sec and final amplification for 7 min at 72°C. Subsequently, 10 μL of amplified product were subjected to restriction with 1 μL of MboI (10 U/μL) according to the manufacturer’s protocol (Canvax, Spain). The restricted products were separated by electrophoresis in 2% agarose gel stained with ethidium bromide.

RESULTS

Bacterial isolates determined as suspicious for S. pseudintermedius based on their characteristics in the conventional microbiological tests until PCR-RFLP analysis was performed are presented in Table 1. The table shows that most (85.44%) of the isolates exhibit a typical S. pseudintermedius profile expressed in the presence of β-haemolysis, a positive test for proving free plasma coagulase within 2-4 h, negative test for acetoin production and β-galactosidase positivity (ONPG test), sensitivity to polymyxin B, acidification of mannitol, trehalose and maltose. Atypical reactions were found in 23 (14.6%) strains with respect to the presence of hemolysins and acetoin production in the VP test. These isolates were respectively γ-haemolytic (2.5%) and VP positive (12.0%). Table 1 also shows the biochemical characteristics of the reference strains included in the study. The coagulase-positive isolates of cats exhibited a variability in VP and ONPG assays and were interpreted as resistant to polymyxin B, which was not in line with the profile for S. pseudintermedius.

The S. intermedius ATCC 29663, S. delphini ATCC 49171 and S. pseudintermedius LMG 22219 reference strains, and the two clinical isolates tested were successfully identified with the BioLog commercial system. The substrates used as carbon sources by the reference strains of the SIG group and two of the isolates identified as S. pseudintermedius with MboI restriction analysis are shown in Table 2. It is obvious that 14 of the substrates are completely utilised from the five strains tested. Only six substrates - stachyose, D-aspartic acid, D-serine, p-hydroxy-phenylacetic acid, D-malic acid and γ-amino-butyric acid, were not metabolised by the species tested, whereas no metabolic activity was recorded against D-cellobiose, D-raffinose, D-melibiose, D-salicin, 3 methyl glucose, L-fucose, L-rhamnose, bromo-succinic acid and β-hydroxy-D, L-butyric acid with exception of one of the strains showing borderline activity. The profile of S. pseudintermedius strains differs only in their inability to use seven substrates as a carbon source, unlike S. intermedius ATCC 29663 and S. delphini ATCC 49171 and, with respect to four substrates, borderline activity or lack thereof in clinical isolates was recorded.

The results of the PCR-RFLP analysis are presented on Fig. 1. The restriction profile of the dog strains suspected to be S. pseudintermedius consisted of two bands at 213 bp and 107 bp, respectively. S. intermedius ATCC 29663 and S. delphini ATCC 49171 did not exhibit the MboI restriction site, whereas the tested S. aureus strains showed a restriction profile with a band of 160 bp. Amongst the cat isolates, the MboI restriction profile specific for S. pseudintermedius was not established.

DISCUSSION

In routine bacteriological examinations, pathogenic staphylococci are frequently identified to the level of coagulase activity and no further identification is undertaken. On the other hand, the incorrect differentiation of

![Table 1: Biochemical profile of the isolates from dogs suspected to be S. pseudintermedius and the reference strains from the SIG group determined on the basis of key assays](image-url)
coagulase-positive staphylococci is quite possible, especially for the representatives of the SIG group, due to their similar biochemical properties. The precise determination of these staphylococci is important for clinical practice with regard to the choice of antimicrobial agent associated with the correct interpretation of the minimum inhibitory concentration.
concentrations and the resulting outcome of therapy \cite{1,8,16}, and because of the established zoonotic potential of \textit{S. pseudintermedius} and \textit{S. intermedius} \cite{11}. In the present study, the isolates with a biochemical profile suspected for \textit{S. pseudintermedius} were selected based on key biochemical markers for primary differentiation of clinically relevant staphylococci in veterinary medicine \cite{15}. Key markers for the differentiation of the three staphylococcal species included in the test panel were the VP test and the ONPG test, which clearly categorised the reference strains. However, atypical reactions were found in \textit{S. pseudintermedius} isolates relative to the production of acetoin in which \textit{S. pseudintermedius} and \textit{S. intermedius} profiles did not differ. The BioLog GenIII phenotypic identification system identified reference strains \textit{S. intermedius} ATCC 29663 and \textit{S. delphini} ATCC 49171 with the highest probability of 1.000, whereas \textit{S. pseudintermedius} LMG 22219 and both clinical isolates with a probability of 0.555 - 0.569, confirming the great biotype diversity of this bacterial species \cite{8}. In this regard, we disagree with Devriese \cite{2} who claims that there is no commercial kit available to identify \textit{S. intermedius} and \textit{S. delphini}. In addition, the updated BioLog system software includes the metabolic profile of \textit{S. pseudintermedius}, which enables accurate identification at the phenotypic level. The carbon sources that did not detect metabolic activity in the reference strain and the clinical isolates compared to \textit{S. intermedius} ATCC 29663 and \textit{S. delphini} ATCC 49171 were N-acetyl-β-D-mannosamine, myo-inositol, L-arginine, L-pyroglutamic acid, mucic acid, quinic acid and Tween 40. Borderline activity or lack thereof in one of the clinical isolates was found against pectin, D-galacturonic acid, L-galactonic acid lactone and acetoacetic acid. With respect to the other biochemical reactions, detailed comparisons with other data published on \textit{S. pseudintermedius} cannot be made due to the different substrates incorporated in the commercially used identification systems - BioLog in our study, API 50CH and API STAPH (BioMerieux), and STAPH-ZYM (Rosco) in the research of Devriese \cite{2}.

The PCR-RFLP method on which accurate identification of \textit{S. pseudintermedius} isolates was based in this study was originally developed by Bannoehr et al.\cite{13}, and has been used successfully in other countries \cite{17,18}. The method was also reproduced in our laboratory after optimisation of temperature parameters for hybridisation of primers at amplification of pta-PCR. The most distinct amplification products of the \textit{pta} gene were visualised at 54°C, and the optimum denaturation, annealing and elongation time for each cycle was determined to be 45 s. Subsequent \textit{MboI} analysis of PCR products of 320 bp clearly differentiates \textit{S. pseudintermedius} isolates having a restriction site resulting in two bands of 213 and 107 bp, respectively. The restriction profile of \textit{S. aureus} ATCC 25922 as well as the five \textit{S. aureus} field strains differed by one visible band of about 160 bp in the agarose gel, which actually consists of two closely spaced bands - 156 and 164 bp, which are not established in the routine electrophoresis \cite{13}. \textit{S. intermedius} ATCC 29663 and \textit{S. delphini} ATCC 49171 are not differentiated by this method as they do not have a restriction site and \textit{MboI} products have not been realised.

The data in our study showed a predominance of \textit{S. pseudintermedius}...
pseudintermedius in clinical samples from dogs. The species affiliation of the isolates found to be suspicious for S. pseudintermedius by conventional methods was confirmed by PCR-RFLP analysis. Only two skin lesion isolates showed no restriction site and could not be determined by the RFLP method. The involvement of S. aureus in infectious pathology in dogs in a previous study of ours was estimated at 16.1%\(^{[19]}\). All these data confirm the prevalence of S. pseudintermedius in dog specimens. With respect to cat isolates, S. pseudintermedius was not detected in any of the samples tested, which is consistent with the data of Bannoehr et al.\(^{[13]}\), who found S. pseudintermedius in only one of the 14 cat isolates tested. Due to the limited number of feline isolates analysed, definitive conclusions regarding the prevalence of S. pseudintermedius in this animal species in our country cannot be made. Obviously, its prevalence ranges from 3.08% in healthy cats to 11.97% in sick cats, values found in Poland in a large animal study cohort\(^{[20]}\). The other isolates did not show a restriction profile and their precise determination will be the subject of future studies based on other modern approaches.

In conclusion, the results of this study demonstrate the usefulness of key biochemical tests to target the SIG group members, but the precise differentiation of S. pseudintermedius, S. intermedius and S. delphini should be based on extensive phenotypic analysis together with molecular biological methods, or the latter alone.
