Abstract
The aim of this study was to investigate the effect of hesperidin on male reproductive system in rats to which methotrexate (MTX) was administered. In the study, 28 male Wistar albino rats at the age of 8 weeks and had 250-300 g of live weight were used. Four experimental groups were formed; Group 1 (n=7): The control group, only feed and water were given. Group 2 (n=7): MTX group, a single dose of 20 mg/kg of i.p. MTX was administered. Group 3 (n=7): Hesperidin group, 200 mg/kg of hesperidin was administered by gavage for 7 days. Group 4: MTX + hesperidin group (n=7): Following administration of a single dose of 20 mg/kg i.p. MTX , 200 mg/kg of Hesperidin was administered by oral gavage for 7 days. At the end of the experiment, rats were decapitated and biochemical, histopathological and spermatological parameters were examined. It was observed that in the MTX group, sperm motility and density, the enzymes CAT, GPx and SOD and GSH level decreased, TNF-alpha and IL-1 Beta, as well as MDA, levels were increased, regular structure of spermatogenic cells was impaired, and seminiferous tubules became necrotic and degenerative. It was determined that spermatological parameters improved and, necrotic and degenerative changes diminished by the administration of MTX+hesperidin. These outcomes indicated that hesperidin had a protective effect on destructive effects of MTX in rat testicles.

Keywords: Male rat, Hesperidin, Methotrexate, Sperm, Reproductive system

Ratlarda Metoraksat Kaynaklı Testiküler Toksisite Üzerine Hesperidinin Etkisi

Özet
Bu çalışmanın amacı, metotrexat (MTX) uygulanan ratlarda hesperidinin erkek üreme sistemi üzerindeki etkisini araştırmaktı. Çalışmada 8 haftalık yaşta, 250-300 g canlı ağırlığa sahip 28 erkek Wistar albino cinsi rat kullanıldı. Dört deney grubu oluşturuldu; Grup 1 (n=7): kontrol grubu, sadece yem ve su verildi. Grup 2 (n=7): MTX grubu, 20 mg/kg MTX i.p. tek doz uygulandı. Grup 3 (n=7): Hesperidin grubu, 200 mg/kg hesperidin 7 gün süre ile ağızdan sonda yardsımla verildi. Grup 4 (n=7): MTX + hesperidin grubu, 200 mg/kg MTX i.p tek doz uygulamasını takiben 200 mg/kg hesperidin 7 gün süre ile ağızdan sonda yardsımla verildi. Deney sonunda ratlar dekapite edildikçe biyokimyasal, histopatolojik ve spermatolojik parametreler incelendi. MTX grubunda sperm motilitesi ve yoğunlüğünün, CAT, GPx ve SOD enzimlerinin ve GSH düzeyinin düştüğü, TNF-alpha ve IL-1 Beta ile MDA düzeyinin arttığı, spermatojenik hücrelerin düzene yapsının bozulduğu, seminifer tubullerinin necrotik ve dejeneratif bir hal aldığı gözlandı. MTX + hesperidin uygulaması ile spermatojenik parametrelerin düzeldiği, necrotik ve dejeneratif değişikliklerin azaldığı tespit edildi. Bu sonuçlar hesperidinin rat testislerinde MTX tarafından oluşan yakıcı etkiler üzerinde koruyucu etkiye sahip olduğunu gösterdi.

INTRODUCTION

Chemotherapeutics are well-known to have an acute toxic effect which influences many organs. One of these effects is testicular toxicity presenting with azoospermia and infertility in males \([1]\). Methotrexate causes defective oogenesis and spermatogenesis \([2]\).

Presence of omega 3 polyunsaturated fatty acids (PUFAs) within the membrane of testicle makes this organ more susceptible to oxidative stress \([3,4]\). There are various antioxidant mechanisms in testicle which neutralize harmful effects of reactive oxygen species. However, MTX application causes an increase in formation of free radicals due to loss of effectiveness of antioxidant mechanisms, alterations in proinflammatory cytokine system and activation of phagocytic cells \([5,6]\). Activation of immune cells via proinflammatory cytokines leads to overproduction of ROS, resulting in overproduction of ROS, which leads to an increase in LP levels, just like MDA. Overproduced ROS interacts with structure and ratio of PUFA2 and leads to loss of fluidity in biological membranes \([4,6]\).

It has been reported in previous studies that MTX leads to reductions in weights of reproductive organs, as well as leads to severe degradation of seminiferous epithelium, reduction of diameter of seminiferous tubules, reduction in size of spermatogenic cells and dilations in interstitial region \([3,4]\).

It has been reported that MTX-induced organ toxicity can be as a result of oxidative stress \([19]\). Therefore, compounds with antioxidant properties may protect testicular tissue from harmful effects of the oxidative stress caused by MTX \([19]\).

The antioxidant known as Hesperidin is a bioflavonoid antioxidant used in traditional Chinese medicine \([11]\). In many studies, it was demonstrated that Hesperidin reduced toxic effects \([11,13]\).

HP has radical clearance and anti-inflammatory effects \([15,16]\). It has been reported that Hesperidin significantly reduces lipid peroxidation in testicular tissue, leads to positive effects on sperm parameters and biochemical parameters, as well as provides improvements in epididymal functions \([14,17]\).

Although protective properties of some antioxidants in rats exposed to MTX have been investigated, protective property of Hesperidin has not been investigated yet. Therefore, in this study, effect of Hesperidin on male reproductive system is investigated at biochemical, histopathological and spermatological levels.

MATERIAL and METHODS

Chemicals

MTX (Ebewe Pharma® Unterach-Austria) was bought from a pharmacy. Hesperidin (Sigma-Aldrich St. Louis, MO, USA) was provided from a medical market. Rat TNF alpha ELISA kit and Rat IL-Beta ELISA Kit were procured from Cayma and other chemicals, however, were procured from Abcam and Merc.

Animals and Experimental Procedure

The study was approved by Yuzuncu Yil University Local Ethics Committee On Animal Experiments (Approval number: 2015/28). The study was performed on 28 healthy male Wistar albino rats (8 week-old, with 250-300 g of body weight) which were provided from Firat University Faculty of Medicine Experimental Research Center (Elazig, Turkey). Animals were adjusted to experimental conditions for a 1-week period before starting dosage. The animals were housed in standard laboratory conditions (24±3°C temperature, 40-60% humidity and 12 h light/12 h darkness). They were fed with commercial pelleted feed (Bayramoglu Food, Erzurum/Turkey) and fresh drinking water was provided ad libitum.

The experimental administrations were done in Experimental Animal Research Center of Yuzuncu Yil University. Rats were divided into 4 experimental groups, with 7 rats in each. Dosages of administered drugs were regulated in accordance with previous studies \([10,14,18]\).

Group 1: Healthy control group (n=7): Only feed and water were given.

Group 2: MTX group (n=7): A single dose of 20 mg/kg of MTX was administered I.P. Because, it was revealed in previous studies that this dose (20 mg/kg) causes tissue toxicity \([19]\). MTX was dissolved in physiological saline.

Group 3: Hesperidin group (n=7): 200 mg/kg of hesperidin was administered by oral gavage for 7 days \([14]\). Hesperidin was dissolved in physiological saline.

Group 4: MTX + hesperidin group (n=7): Following administration of a single dose of 20 mg/kg MTX I.P, 200 mg/kg of Hesperidin was administered by oral gavage for 7 days.

Twenty-four hours after the last administration, the rats were decapitated under mild anaesthesia with sevoflurane. One of the testicular tissues was taken for biochemical analyses and kept under -80°C, and cauda epididymis of the other testicle was taken for spermatological examinations and the related testicle was fixed in Bouin’s solution \([20]\).

Collection of Samples and Evaluation of Spermatological Features

Testicles were removed. In order to obtain sperm from cauda epididymis, the method which was previously described by Sonmez et al. \([21]\) was used. Briefly, epididymis is minced within 1.0 mL of physiological saline (0.9% w/v NaCl) by using an anatomical scissor in a petri dish. In order to provide transition of all spermatozoa into the fluid, it was left for incubation for 15 min. The obtained fluid was used as a sperm sample.
Sperm density was determined by using a slight modification of the method described by Sonmez et al\[21\]. Sperm sample was poured into an eppendorf tube via an automated pipette with 10 µL of volume and 990 µL of eosine solution was added. Approximately 10 µL of diluted sperm suspension was transferred to counting chambers of a thoma slide (HHH Germany) and 5 min were awaited. They were counted at 200x magnification under phase contrast microscopy and calculated by using the formula used for calculation of sperm density.

Percentage of sperm motility was evaluated at 200x magnification by using a light microscope with a heating stage (ECLIPSE E 400 Nikon JAPAN), as it was stated by Sonmez et al\[21\], Average of three consecutive evaluations was used as the final motility score.

In order to evaluate abnormal sperm cells, the method which was reported in the study conducted by Turk et al\[22\] was used. Briefly, one drop of sperm sample was mixed with the same amount of eosine-nigrosine staining (1.67% eosine, 10% nigosine, and 0.1 M sodium citrate) and thin smear was prepared. 300 sperm cells were examined at 400x magnification under light microscope.

**Biochemical Evaluations of Testicular Tissues**

The testicular tissue which was triturated in porcelain mortar by using liquid nitrogen was diluted with 1.15% KCl and homogenized within ice with IKA-T-18 BASIC model ultra turrax. Firstly, obtained homogenate was centrifuged at 3500 rpm for 15 min and then the supernatant portion was separated for determination of protein, malondialdehyde, glutathione, superoxide dismutase and catalase.

The testicular tissue which was weighed according to dilution rate was diluted with 1.15% KCl and homogenized within ice by IKA T-18 BASIC ultra-turrax homogenisator. After the homogenate was centrifuged at 11.000 rpm for 20 min, the supernatant portion was separated for determination of glutathione peroxidase.

Determination of MDA was performed with thiobarbituric acid reaction method, which was reported by Placer et al\[23\]. Measurement of GSH level was performed in accordance with the method reported by Sedlak and Lindsay \[24\]. SOD activity was performed with the method reported by Sun et al\[25\]. SOD activity is measured via absorbance at 560 nm demonstrated by farmasone within the formed coloured solution. GPx activity was measured with the method of Aebi \[27\]. CAT activity in the testicular tissue was demonstrated by farmasone within the formed coloured solution. SOD activity was measured with the method reported by Sonmez et al\[21\]. Average of three consecutive evaluations was used. P<0.05 value was accepted to be significant.

**Histopathological Evaluations**

Obtained testicular tissues were fixed in Bouin’s solution for 24-48 h. Tissues taken into paraffin blocks were passed through routine alcohol-xylol series. Slices which were sectioned 5 µm in thickness were stained with hematoxylin-eosin and examined under light microscope. For histopathological evaluation, Johnsen’s testicular biopsy score was used \[20\].

**Immunohistochemical Evaluations**

Following deparaffinization, the slices were treated with 400 watts antigen retrieval solution (pH 6.0) in microwave oven for 15 min. To prevent endogenous peroxidase activity, it was awaited within 3% H2O2 for 10 min Slices washed with PBS were incubated for 15 min under room temperature with 8-OhDG primary antibody (cat no. Sc-66036, dilution ratio 1/200, Santa Cruz Biotechnology USA) and anti-NFKB1 antibody (cat no. ab7971, dilution ratio 1/200, Abcam, USA). Slices washed with PBS were continued to be stained with expose mouse and rabbit specific HRP/DAB detection IHC kit. 3,3’ diaminobenzidine (DAP) was used as a chromogen. Slices which were passed through alcohol xylol series following counterstaining with hematoxylin were examined under light microscope. Immunopositivity was evaluated as none (0), mild (1), moderate (2) and severe (3).

**Statistical Analysis**

All statistical data were evaluated by using SPSS program (SPSS for windows, version 20.0). Spermatological and biochemical data were evaluated with Post hoc Tukey-HSD test and One-way variance analysis (ANOVA) in order to determine the differences between the groups. For histopathological and immunohistochemical findings, non-parametric Kruskal-Wallis and Mann-Whitney-U tests were used. P<0.05 value was accepted to be significant.

**RESULTS**

**Spermatological Parameters**

Sperm density, motility and abnormal sperm rate are given in Table 1. MTX group exhibited a significant decrease in sperm density and motility and a significant increase in
Investigation of Effectiveness of... 

abnormal sperm rate, compared to the control and other groups. In addition to this, it was determined that MTX with Hesperidin treatment reduced the increased abnormal sperm rate and increased the reduced sperm motility and sperm density, compared to the only MTX group (Table 1, P<0.05).

**Biochemical Results**

Biochemical results of the testicular tissue are given in Table 2. It was determined that in the testicular tissue, MDA level increased in MTX group compared to the control group and MTX + hesperidin administration lowered this level to a near value in the control group (P<0.05). It was also determined that GSH level reduced in MTX group and MTX + hesperidin administration increased this lowered level (P<0.05).

It was determined that CAT, GPx and SOD activities were lower in the MTX-treated group compared to the control group, MTX + hesperidin administration led to an increase in enzyme activities and strengthened antioxidant defence system (P<0.05).

When the testicular tissue was examined in terms of TNF-alpha and IL-1 Beta levels among cytokines, it was determined that the levels were significantly lower in the group for which hesperidin was administered alone, compared to the control group. With MTX administration, increase in TNF-alpha and IL-1 Beta levels occurred, and addition of hesperidin treatment to MTX treatment was observed to decrease TNF-alpha and IL-1 Beta levels (P<0.05).

**Histopathological Findings**

Structure of seminiferous tubules was observed to be normal in the control and hesperidin groups (Fig. 1A-1B). It was recognized that in the group for which MTX was administered, regular structure of spermatogenic cells was impaired, and seminiferous tubules became necrotic and degenerative, with development of sporadic flaking (Fig. 1C). It was determined that in the group for which MTX was administered together with hesperidin, observed necrotic and degenerative changes were reduced compared to the group for which MTX was administered alone (Fig. 1D, Table 3, P<0.05).

Immunohistochemical Findings

8-OhDG expression was determined to be extremely low in control and hesperidin groups (Fig. 2A-2B). It was determined that in the group for which MTX was administered alone, 8-OhDG was expressed strongly in seminiferous tubules but 8-OhDG expression level decreased in the group for which MTX was administered together with hesperidin (Fig. 2C-2D, Table 4, P<0.05). NFKB1 expression, however, was at extremely low level in control and hesperidin groups (Fig. 3A-3B). Whereas it was observed that NFKB1 was expressed strongly in spermatids in the group for which MTX was administered alone, expression level was observed to begin decreasing in the group for which MTX was administered together with hesperidin (Fig. 3C-3D, Table 4, P<0.05)

DISCUSSION

Testicles are the most important target organs for oxidative stress due to their high content of polyunsaturated membrane lipids [29]. Increased oxidative stress in testicles damages to spermatological parameters [30].

In the current study, the decrease in sperm count and sperm motility and the increase in abnormal sperm rate determined following MTX administration confirmed previous studies [7,18,31]. The increase in abnormal sperm rate and reduction in sperm density and motility are associated with the increased lipid peroxidation. This situation can be explained by that MTX damages cell membrane integrity by disturbing lipids and proteins within the sperm membrane. It was determined in previous studies that like MTX, Cisplatin causes a marked decrease in sperm density and motility [32-34].

Hesperidin administration in addition to MTX decreased effects of MTX on sperm parameters and increased sperm count and motility. Protective effects of hesperidin are probably may be referred to its obvious antioxidant potential which was observed in this study.

Our biochemical findings indicated that MTX increased MDA level which is among the most important oxidant parameters in the testicular tissue, compared to the control group. This finding is consistent with some reports indicating that MTX stimulates oxidative stress by increasing MDA levels [8,10,35]. Also, it revealed that MTX treatment significantly decreased endogenous antioxidant enzyme activities such as SOD, CAT and GPx and GSH level, which are commonly used for monitoring oxidant/antioxidant status. In the study, it was determined that Gpx, CAT and SOD enzyme
activities, as well as GSH level, were significantly increased and lipid peroxidation induced by MTX was significantly reduced with hesperidin administration. These results are consistent with those of previous studies [14,17,36].

TNF-alpha exists in seminiferous tubules and is strongly up-regulated under both pathological and physiological conditions [37,38], IL-1 Beta is produced by macrophages. This cytokine is known as an important mediator of various cellular functions, including reproduction, differentiation and apoptosis, and of the inflammatory response [39]. The increase in TNF-alpha and IL-1 Beta levels which was observed after MTX administration suggested that MTX led to an inflammatory reaction. Reduction of this increase in TNF-alpha and IL-1 Beta levels by administration of hesperidin in addition to MTX suggests that hesperidin has anti-inflammatory effects. It was reported in a previous study that Cisplatin, Doxorubicin and Sodium nitrite increase TNF-alpha and IL-1 Beta levels among pro-inflammatory cytokines in testicular tissue [40-42].

In histopathological evaluation, severe necrotic and degenerative changes were determined in MTX group. In MTX + hesperidin group, however, necrotic and degenerative changes were determined to be milder. Therefore, possible protective effect of hesperidin was evaluated immuno-histochemically with 8-OhDG in regard to DNA damage and with NFkB in regard to inflammatory reaction. 8-OhDG is a form of free radicals and a biomarker used in oxidative stress [43]. In various studies it was expressed that severity of DNA damage in testicular destruction due to oxidative stress was determined with 8-OhDG [44]. In the present study, whereas 8-OhDG was strongly expressed in MTX group, reduction in 8-OhDG expression in the group for which MTX was administered together with hesperidin suggested that DNA damage was diminished and, hence, hesperidin had a protective property. NFkB, however, is a molecule which is activated when oxidative stress is developed [45,46]. It was reported that level of NFkB increased with testicular intoxication [47,48]. Present study, NFkB was determined to be severe in MTX group and moderate in MTX + hesperidin group. This situation was expressed as that hesperidin reduced inflammatory reaction.

This study demonstrated that administration of a single dose of 20 mg/kg of MTX increased lipid peroxidation levels in testicles of Wistar albino rats and, thus, caused oxidative stress. Additionally, it also demonstrated that
it had toxic effects including histopathological changes and spermatological damage. Treatment of MTX together with hesperidin was determined to significantly prevent toxicity of MTX on reproductive system. When results of all groups are taken into consideration, we suggest that hesperidin has a regenerative effect on testicular tissue and sperm parameters.
