Abstract

Parathyroid cell transplantation is an effective approach for the treatment of permanent hypoparathyroidism. Intramuscular and intraperitoneal routes were performed previously but intravenous administration has not been conducted previous studies. Our aim is to determine proper homing site for parathyroid cells, therefore we administered parathyroid cells intravenously and observed results. This study is carried out on nine sheep. According to the given substance the sheep were divided into two groups; seven were parathyroid cell injected group and two were isotonic saline solution injected control group. Parathyroid cells were obtained from a patient with chronic kidney failure and were injected intravenously into sheep after cell isolation: 20x10^6 cells for two animals, 50x10^6 cells for two animals, 100x10^6 cells for two animals, and 200x10^6 cells for one animal respectively, with no post injection immunosuppresive therapy. Physical conditions of animals and blood biochemical tests were observed for three months. After sacrifices, kidneys and livers were evaluated histopathologically. In 20x10^6 and 50x10^6 cell transplanted groups serum PTH levels increased in the first seven days but in the other groups remained stable. Histopathological evaluations of kidneys and livers revealed fibrosis related to the number of infused cells, however biochemical functional differentiations were not detected. Intravenous parathyroid cell transplantation is considered as an effective and useful technique to perform without immunosuppression. However, further and long term studies need to have more acceptable results in future for clinical purpose.

INTRODUCTION

Permanent hypoparathyroidism (PH) is a clinical condition accompanied by hypocalcemia, hyperphosphatemia, and low parathormone (PTH) levels. The most common etiologic factor of PH is thyroid surgery [1]. The current standard treatment of PH is vitamin D and calcium supplementation. Standard treatment only relieves the symptoms temporarily and may cause several side effects [2]. Recombinant parathyroid drugs reveal better results however balancing the dosage, efficacy, and safety is not clear. In addition, recombinant parathyroid drugs are more expensive than standard treatment [3]. Parathyroid cell transplantation is the most promising technique for the treatment of PH [4]. In the literature, several transplantation approaches have been reported such as auto-transplantation [5], allo-transplantation [6], and xenotransplantation [7](XT). These approaches are used with different methods e.g. direct tissue injection [8], non-treated cultivated cells injection [9], cultured parathyroid cells treated with IFNγ [10], macroencapsulation [11], and microencapsulation [12]. Different experimental animal models for the assessment of parathyroid function, morphology, and disease progression have been investigated including, dog [13], rat [14], rabbit [15], and sheep [16]. Among them parathyroid transplantation models were assessed by intramuscular [17] and intraperitoneal routes [7], respectively. Till the time of the research was planned, intravenous parathyroid cell transplantation has not been tried. In the present study, we injected human parathyroid cells to the sheep, and observed the functionality of the cells and their effects on the kidney and liver.

MATERIAL and METHODS

The study was approved by the Bezmialem Vakif University, Local Experimental Animals Ethics Committee (approval number: 2018/12). In the power analysis, the number of subjects was determined in 85% confidence interval and 95% significance level. We studied on nine sheep (12 months-old, mean weight 27.05 kg, weight range 24.5-35.5). The animals were housed and fed ad libitum throughout the study. The animals were divided into two groups: intravenous parathyroid cells injected group (n=7) and intravenous isotonic saline solution injected group (n=2). Peripheral blood samples were obtained before XT and continued biweekly after XT for 90 days. Weights and other physical conditions of the animals were observed the functionality of the cells and their effects on the kidney and liver.

Tissues were evaluated by one expert pathologist who blinded the groups, according to fibrosis scoring (Grade 0: No fibrosis for liver and no congestion/fibrosis for kidney, Grade 1: Mild fibrosis for liver and mild congestion/fibrosis for kidney, Grade 2: Moderate fibrosis for liver and moderate congestion/fibrosis for kidney, and Grade 3: Severe fibrosis for liver and severe congestion/fibrosis for kidney) as previously reported by Idiz et al. [18]. Before the XT procedure the Local Human Ethics Committee approval was received (approval number: 71306642-050.01.04). All of the protocols were confirmed according to the ethical guidelines of the Helsinki Declaration and written informed consent was obtained from the donor. The donor patient was a 34 year old man with parathyroid hyperplasia resistant to drug therapy due to chronic renal failure who was referred from the nephrology outpatient clinic to the general surgery department for surgical intervention. Standard subtotal parathyroidectomy procedure was performed and half of each of the resected glands were delivered to the pathology laboratory for histopathological evaluation. The remaining parts of the glands were snap frozen. After the histopathological evaluations were reported as benign parathyroid hyperplasia, the tissues were prepared for the XT process.

Cell Preparation Procedure for XT

In laboratory conditions, the tissue was cut and washed with 1% Phosphate-buffered solution (Thermo Fisher Scientific, MA) and minced in a petri dish on ice. The minced preparation was combined with 2 mL for a total 100 mg/mL bovine serum albumin (Merck Millipore, Germany), 215 mmol collagenase type II (Thermo Fisher Scientific), 0.32 mM DNase I (AppliChem, Gatersleben, Germany), and 1 mL Ham’s F10 Supplement (Thermo Fisher Scientific). Samples were transferred to an incubator (CCL-1708-8; ESCO, Singapore) at 37°C with humidified atmosphere containing 5% CO₂, where they were incubated overnight. Each sample was centrifuged at 306 g for 15 min to obtain a pellet. Cells were suspended in 1 mL of culture medium. Parathyroid cell viability was assessed before cryopreservation using a Muse Cell Analyzer (Merck Millipore) with a Muse Count & Viability Assay Kit (Merck Millipore) [19]. The cells were mixed with 10% DMSO (dimethyl sulfoxide), 10% FBS, and suspended in cryotubes kept at -80°C, and then transferred to a liquid nitrogen tank for storage. The day before XT, cells were removed from the nitrogen tank and cultivated in flasks with McCoy’s 5A (Modified) Medium (Thermo Fisher Scientific) with 1% sodium pyruvate, 1% penicillin-streptomycin, and 10% FBS and placed in an incubator (CCL-1708-8; ESCO) at 37°C with 5% CO₂ humidified atmosphere, where they were kept overnight before XT.

XT Procedure

Prepared xenograft cells were administered to seven animals
by a decreased count system: 100x10^6 cells for two animals, 50x10^6 cells for two animals, and 200x10^6 cells for one animal into the 10 mL isotonic saline solution. Injections were performed via external jugular vein catheterization. In the control group, 10 mL isotonic saline solution physiologic was injected intravenously via the external jugular vein.

**Blood Biochemical Tests**

Serum sheep-PTH and human-PTH levels were measured using Sheep Parathyroid Hormone ELISA Kit* (MyBiSource, CA, USA) and Architect Intact hu-PTH Assay Kit* (Abbott, IL, USA), respectively. A complete blood count (CBC) was measured by Hematology Analyzer Abacus Junior Vet* (Diatron, Budapest, Hungary). Aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma-glutamyl transpeptidase (GGT), alkaline phosphatase (ALP), lactate dehydrogenase (LDH), troponin, creatine kinase (CK), amylase, lipase, urea, total bilirubin, calcium, phosphorus, albumin, and creatinine were measured by Chemistry Analyzer IDEXX VetTest® (IDEXX Laboratories, Maine, USA).

**Statistics**

All data during the given period were compared with pre-op values. Statistical analyses were performed using SPSS software v22.0 (IBM, Armonk, NY, USA). Data was not normally distributed, thus we used Friedman test as a non-parametric test, and P<0.05 was considered statistically significant.

**RESULTS**

Mean blood biochemical parameter variations, except PTH in the XT group are presented in Table 1. No statistically significant changes were detected (P>0.05). Mean blood PTH level variations in the XT group is presented in Fig. 1. In the 20x10^6 and 50x10^6 cell injected groups, PTH increased for the first five days after XT and, then decreased (Fig. 1-A,B). In the 100X10^6 cell injected group, PTH decreased gradually after XT, but increased slightly between 30 to 60 days (Fig. 1-C). In the 200x10^6 cell injected group PTH increased gradually after XT, however it did not reach the normal level. According to the non-parametric Friedman test, PTH levels were not detected statistically significant (P=0.393). All changes in the PTH levels were compiled in Fig. 1.

**DISCUSSION**

Several therapeutic approaches are available for PH treatment, among them the most effective approach is parathyroid allotransplantation. The first parathyroid allotransplantation was reported in 1911 [20]. Between 1990-2016, 316 allotransplantation cases were published in the literature and most of them were performed via intramuscular routes [5]. Three major routes are defined for cell type transplantations intramuscularly, intraperitoneally, intravenously, etc...

and intravenously \([7,21]\). The acceptable route for parathyroid cell allotransplantation has not been determined with the best results yet \([22]\). Intramuscular route is routine way for cell type transplantations because it is easy and quick to perform, but the rate of success varies between the centers \([8,23]\). Different results could be due to technical preparation of details related to cell manipulation or immunological responses.

On the other hand, according to the Kimura et al.\([24]\), PTH enhances myocyte differentiation by stimulating myotubes and accelerated muscle strength may increase mechanical stress for the transplanted parathyroid allo-graft. Therefore, intramuscular transplantation may increase mechanical stress on transplanted parathyroid cells by muscle strength. Intraperitoneal cell transplantation is a traditional technique but has been popular nowadays \([25]\) and some clinicians use the route for therapy. Several types of cells such as islet cells \([26]\) and Sertoli cells \([27]\) were transplanted via the intraperitoneal route. The main advantages of intraperitoneal administration are low intraabdominal pressure and rich vascular structures, as omentum. A disadvantage of the route is that surgical intervention is required under general anesthesia \([28]\). Intravenous cell transplantation mainly utilize hematopoietic stem cells for bone marrow related hematologic disorders \([29]\). In addition, islet cells \([30]\) and mesenchymal stem cells \([31]\) were transplanted intravenously as well. The portal vein is the routine access for transplantation of islet and mesenchymal stem cells \([27]\) but the portal vein route is associated with cell loss and poor engraftment due to instant blood-mediated inflammatory reaction (IBMIR). Once transplanted cells trigger IBMIR, a significant amount of injected cells die or lose their functions \([32]\). In intravenous transplantation, homing site of transplanted cells is the optimal way for determination of success rate. Whether transplanted cells are positive for CD-34 surface protein, they migrate to the bone marrow directly. CD surface proteins of parathyroid cells have not been detected yet therefore their homing site is uncertain. In this study, we evaluated histopathologically liver and kidney tissue for potential homing sites of parathyroid cells. We postulated that transplanted parathyroid cells may be homing to the liver and kidney due to the membranous protein similarity or joined with their microcapillaries. We detected inflammatory reactions lead to fibrous tissue related to the number of transplanted cells in the liver and kidney, and no parathyroid cells in their tissue histopathologically. So any functional changes were not seen in profile levels of liver and kidney. Serum PTH levels increased during the first seven days in the 20×10^6 and 50×10^6 cell XT animals. Allotransplantation instead of XT with less number of cells may cause higher serum PTH levels with a longer period of time without histopathological damage to the major organs such as the liver and kidneys. As a conclusion, our results are promising as a new treatment option for the treatment of PH. However, long term follow-up studies with a different number of cells are in need before clinical trial.
